Personal Consumption Expenditures in the 1958 Input-Output Study

HIS article extends the information on personal consumption expenditures that was made available in the 1958 input-output study.1 It discusses the relationship between the industry classification scheme used in the inputoutput (or interindustry) tables and the categories used for personal consumption expenditures (PCE) in the national income and product accounts. It thus provides, on a more detailed basis than has been available up to now, information on the industrial composition of PCE and, among other things, on the relative importance of the costs of distribution (trade and transportation). For convenience, this article repeats the information presented in November 1964 on the direct and indirect effect that PCE had on each industry in 1958; a new feature is that these effects are shown separately for each of the three major types of PCE: durable goods, nondurable goods, and services. In addition, this article compares four sets of estimates of the industrial composition of total PCE in 1964. Finally, tables with a detailed comparison of the 1947 and 1958 industrial composition of PCE are presented.2

Definition of personal consumption expenditures

Personal consumption expenditures are the largest component of the Nation's output as measured by GNP; in 1964, they comprised 63 percent of

NOTE.—Jean R. Fratier made a significant contribution in preparation of table).

2. The research for this article was financed by the Interagonor Growth Study. the total. PCE consists of the market value of goods and services purchased by individuals and nonprofit institutions rendering services to individuals and the value of certain imputed goods and services received by individuals as income in kind.

The "commodity flow" method is the basis for the estimates of PCE in both the 1958 input-output flow table and the national income and product accounts. In this method, all goods destined for personal consumption are identified from the output records of farms, factories, etc., and the flow of output is followed through the distribution channels where the costs of transportation, of trade (measured as gross margins inclusive of retail sales and excise taxes), and of certain types of insurance are added to the producers' values to arrive at the prices paid by persons.

Although PCE in the aggregate is identical in GNP and in the inputoutput flow table for 1958, there are, on a detailed basis, important differences in classification between the two sets of accounts. In the GNP tables, consumption expenditures are classified by functional category; in the interindustry tables, they are classified by producing industry. For example, in GNP the classification "food expenditures" consists of the following functional categories: food purchased for off-premise consumption; purchased meals and beverages; food furnished government (including military) and commercial employees; and food produced and consumed on farms. In the inputoutput flow table, on the other hand, "food expenditures" as such are not explicitly shown. However, the PCE column includes flows from the various industries that produce and distribute food: livestock and livestock products (1), other agricultural products (2), forestry and fishery products (3), food and kindred products (14), transportation (65), and trade (69).

The treatment of transportation and trade margins poses a special sort of classification problem since it requires that a distinction be made between producers' prices and purchasers' prices. In GNP, personal consumption expenditures (like all final purchases) are always shown in final purchasers' prices. "Food purchased for off-premise consumption," for example, typically reflects prices actually paid in retail food stores and thus includes all costs to the consumer, including the cost of transportation and of wholesale and retail distribution. In the interindustry flow table, on the other hand, values are shown at producers' prices. That is, goods and services are valued at the prices that producers charge. (These prices, by convention, include excise taxes levied on the producer.) It is these producers' values, in the case of items destined for personal consumption, that are allocated to the PCE column. The transportation costs and trade margins (operating expenses plus profits of wholesalers and retailers) necessary to bring the goods to consumers are shown separately in the PCE column as consumer purchases from the transportation and trade industries respectively. By convention, the costs of trade to the consumer include retail excise taxes and sales taxes. The entry in the trade row

i. The first report an the 1988 study, "The Interindustry Structure of the United States, A Report on the 1938 Impat-Output Study," appeared in the November 1984 Survey or Ourseasy Brustass. The September 1985 Survey presented the basic flow table, in dollar values, underlying the tables first presented but November; the flow table (and the other tables shown with it) incorporated infact revisions of the tables issued earlier.

^{3.} The revised estimates of PCE incorporate some definitional changes, of which the most important is the elimination of the payment by persons of interest on personal dabt, A description of these changes and the revised figures for PCE from 1929 to the current period, in total and by major type, appear in the August 1965 Suavey. The full breakdown of PCE into 63 entegories for this period will be published in a forthcoming supplement.

^{4.} These impulsed Items are: (1) the space-rental value of contended houses (but not the purchase of new dwellings, which are considered capital goods); (2) the value of food, elething, and housing farmished in kind to government (including military) and business employees; (3) food and fuel produced and consumed on farms; and (4) services readered to individuals and nonprofit facilitations by financial intermediaries (except insurance companies) without explicit charge.

^{6.} Table 1, Interindustry Transactions, 1958, Survey, September 1966, page 34.

"Lest then \$500,000."

The numbering scheme of the personal consumption expenditure categories corresponds to the table "Personal Consumption Expenditures, by Type of Product" to be published in a inchemning supplement to the Survey or Curaent Business. With the anceptions bottnoted, the category numbers also correspond to the table 14 in the July 1984 Survey.

Expenditure categories VII-5 and XII-3 in the July 1964 table have been confided because these beens are no longer included in personal consumption expenditures.

Industry number relates to the numbering solvense used for the 1948 input-output study. For some and Standard Industrial Conscillention (SIO) coverage of each industry, see the table at the end of this article.

Change in definition from old category V-8c, Water.

Othings in definition from old category VII-1, Brokerage charges and interest, and investment counseling.

3 Punemt and he															 harad 3		

Funeral and buriel expenses, formerly numbered VI-8.
Imported ears do not appear as a parchase from the import industry (number 80) but are included in the motor vehicles industry (number 69). The import data on outes and parts used for the 1958 isput-output study did not distinguish between assembled and unstablished cars. The total value of such imports was transferred to industry 59 for distribution.

NOTE. — Detail may not said to total due to rounding.

Expanditures in the United States by foreigners, formerly numbered XII-4.
 Does not correspond to old entegery XII-4.

under the PCE column in the flow table includes the cost of distributing all items of PCE through trade channels. The section that follows provides some detailed examples of the foregoing discussion.

Industrial Composition of PCE, 1958

TABLE 1 makes clear the relationship between the interindustry flow table and the GNP accounts in the treatment of personal consumption expenditures. It shows consumption expenditures for each of the 83 functional categories (PCE category) in the GNP accounts. Within each category, it shows the industrial breakdown of expenditures by input-output industry in producers' prices, plus each element of margin transportation, trade, and insurancewhich is added on to arrive at purchasers' prices.6 The industry titles and their definitions in terms of the Standard Industrial Classification (SIC) are shown in the table at the end of this article.7

Gross imports (industry 80): Nearly every one of the PCE categories shows some purchases from the import industry. Under the convention adopted in the 1938 study, imports purchased by the final demand sectors have been shown as a direct purchase from the import row. (On the other hand, imports used for further processing, if they were like domestic goods, have been transferred to the domestic mutatry graduoing similar goods and distributed along with the domestic production of those goods. Imports used for further processing the first table at direct purchases by the processing industry from the import row.)

In "food purchased for off-premise consumption" (category I-I), \$41,426 million represents the value of food at prices charged by producers. The industrial composition of this value can be seen by reading down the first column: \$1,486 million of livestock and livestock products (industry 1), \$1,522 million of other agricultural products (industry 2), etc. The total transportation margin of \$2,219 million for the entire category shown in the second column represents the sum of the individual transportation costs applicable to each producing industry. For example, \$53 million was the cost of transporting livestock and livestock products (industry 1) to consumers; \$549 million was the transportation cost involved in bringing the products of industry 2 to consumers, and so on. The costs of wholesale and retail distribution applicable to each producing industry are shown in the third column. For example, of the total margin of \$14,760 million of wholesalers and retailers in category I-1, \$504 million was required for the distribution of products of industry 1. Purchases of insurance from industry 70 (finance and insurance) are shown in the next to last column only to the extent that they apply to imported goods.

The total transportation margin of \$2,219 million and the trade margin of \$14,760 million are added to the producers' value of "food for off-premise consumption" to arrive at the purchasers' value of \$58,406 million. This last figure appears as item I-1 in the PCE table scheduled for publication in the near future. The industrial composition of this total in purchasers' prices, i.e., retail value, is shown in the last column. In table 1, the transportation margin and trade margin for the products of any given industry are shown along the row for that industry. In this way, table 1 provides measures of the transportation and trade costs involved in bringing goods to consumers, separately for each producing industry and for each PCE category.

It should be noted that the retail component of the trade industry has been defined to include certain activities beyond those of the conventional retail store. For example, in "purchased meals and beverages" (category I-2). the \$7,187 million trade margin includes not only the wholesale markup on food sold by food producers to restaurants but also the entire restaurant markup over the delivered cost of food. (The \$7.813 million in producers' prices represents sales of food from the producing industries before the addition of distribution costs.) Also, the value of the professional services of optometrists are classified as a retail trade activity for the purposes of the inputoutput table. Payment for their services is part of the trade margin in "ophthalmic products and orthopedic appliances" (category VI-2).

An industry may appear in more than one PCE category in table 1. Listings for industry 14 (food and kindred products), for example, appear under 4 of the 83 PCE categories. To obtain the total allocation of any particular industry to PCE it is necessary to sum the several entries for the industry in table 1.

The summation of all entries for the transportation, trade, and insurance

Excluded are certain categories of impated expenditures which have no margin.

^{6.} These same data, in alightly different form, were shown in table C of the November 1966 SURVEY article for PCE classified into 12 broad extegories.

^{7.} For a discussion of the way in which output of the various industries is defined in the 1958 study, see pages 16 and 17 of the November 1966 Sugary. Only a few points considered necessary to an understanding of the figures in table 1 of this article are summarized here.

Purchases represent primary profiteds of an industry: The purchase by consumers from any given demestle industry measures the purchase of that industry's primary product, whether produced in the primary industry ar, as secondary product, in another industry. This is because all secondary products of an industry are transferred (treated as if sold) to the industry to which they are primary; they sugment the output of the industry to which they are transferred.

Scrap, used, or secondhand goods (industry 83): Constimer purchases from this industry as shown in the first column of table I represent purchases by the personal sector from other final demand sectors less personal sales to other final demand sectors. (Sales within the personal sector do not affect the first column because they cancel.) However, the trade morgin has been measured on all sales of used goods-both within the personal sector and between persons and other sectorsto the extent that such sales pass through trade channels. This margin is osually the largest part of the value of used goods in purchasers' prices. Thus, for used care (part of category VIII-la), purchases in 1988 from industry 83 amounted to \$1,379 million, of which \$1,324 million was margin. The value of \$53 million in producers' prices represented the small net sequisition by persons of used care from other final demand sectors.

Source; U.S. Department of Commerce, Office of Business Economics.

industries requires the addition of both "margin" and "nonmargin" purchases. Nonmargin purchases refer to those services that consumers buy directly from airlines, railroads, bus companies, etc. (industry 65); these are shown, for example, in the producers' prices column of table 1 under category VIII-2a and VIII-3c. To these must be added the "margin" purchases from the transportation industry to get total purchases by persons from the transportation industry.

The only nonmargin purchase from the trade industry (number 69) is tips, which appear in the producers' prices column of table 1 under "purchased meals and beverages." Margin purchases from this industry far exceed the nonmargin purchases.

Consumer purchases from industry 70 (finance and insurance) include health insurance (see category VI-7) and bank service charges (see category VII-2). The margin purchases from this industry shown in table I cover only the cost of insuring imported commodities while in transit. (Insurance on domestic products is included in the transportation margin.)

Producer-purchaser prices

Table 1 provides useful information on the size and distribution of transportation and trade margins as defined in the input-output system. Of total PCE in purchasers' prices, transportation margins account for almost 2 percent and trade margins 21 percent; the residual of 77 percent is, of course, producers' value. The share of the consumers' dollar which goes to the producer is 61 percent for durable goods and 63 percent for nondurable goods.

Table 2 and chart 5 show the ratio of producers' value to purchasers' value for each PCE category, with categories arranged in descending order according to that ratio. The median is 57 percent (producers' value as a percent of purchasers' value). "New cars and net purchases of used cars," with 72 percent of the total value going to producers, shows the largest ratio (or the smallest relative distribution costs as defined here). "Food for off-premise consumption" also shows a high ratio, with 71 percent of the consumer's

I Excluded use certain cotagories of imputed expanditures which force no margin

dollar going to the food producer. It should be borne in mind that the inclusion of restaurant markup, the services of optometrists, and retail excise taxes and sales taxes in the retail trade industry affects the spread shown for the various PCE categories.

Industrial composition: three major types of expenditure

The values in table 1 in producers' prices have been reorganized to show the industrial composition for each of the three major types of personal consumption expenditures: durable goods, nondurable goods, and services. Table 3 shows this summary in percentage terms. Column 1, which applies to the total, corresponds to the PCE column in table A of the November 1964 article, except that the latter was based on preliminary figures.

From table 3, it is apparent that the largest share of expenditures on both durable goods and nondurable goods was for trade (industry 69). Aside from trade, the largest share (24 percent) of durable goods expenditures was accounted for by the motor vehicles and equipment industry (number 59), and the largest share (33 percent) of nondurable expenditures was for food and kindred products (industry 14). The largest part (36 percent) of service expenditures was for real estate and rent (industry 71). A significant proportion of real estate and rept expenditures represented the value of imputed rent for owner-occupied housing.

Industrial Impact of PCE

PERSONAL consumption expenditures make a direct demand on numerous industries-automobiles, apparel, food, furniture, to mention a few. While measures of this direct reliance of the producing industry on consumer demand are important, it is a unique contribution of the input-output system that it permits the computation of the indirect effects of PCE on each industry. For example, furniture bought by persons is a direct demand on the furniture industry. The lumber and upholstery fabrics used in the manufacture of the furniture are indirect demands of consumer expenditures on the lumber and textile industries. These two industries

				٠ '	•						1		·	

in turn require the products of other industries; for example, the lumber industry requires chemicals and plastics, the textile industry requires cotton and wool, and so on. The cumulative effect on each industry of all the indirect flows generated by personal consumption expenditures is called the indirect demand attributable to PCE. Direct and indirect effects on each industry of total PCE (and each other major component of final demand) have already been published in table B of the November 1964 article.

The first three columns of table 4 repeat the information previously published by showing the percent of each industry's output attributable to PCE, directly, indirectly, and in total. The remaining columns are new and show similar information for durable goods, nondurable goods, and services.

PCE constituted 65 percent of GNP in 1958. Its importance is also reflected in the total effects on the various industries. Of the 82 industries, 50 attributed more than half of their output to PCE, directly and indirectly, and 19 attributed more than 80 percent to PCE.

As one might expect, most of the output of industries that produced mainly finished goods was attributed to the direct demand of PCE. For example, 90 percent of the total output of tobacco manufactures (industry 15) was attributed to PCE; 72 percent of the total was purchased directly by persons. On the other hand, the indirect demands were large for industries producing mainly intermediate goods. For example, less than 2 percent of the output of chemicals (industry 27) was sold directly to persons in 1958, but an additional 52 percent was indirectly required to meet the demands generated by PCE. The glass industry (number 35) was also heavily dependent on PCE via the indirect flows. Although PCE required only 6 percent of this industry's output directly, it required an additional 62 percent of its output indirectly. The transportation and warehousing industry (number 65) was substantially dependent on both the direct and indirect demands of PCE. Twenty-five percent of this industry's output represented direct sales to persons—for passenger transpertation and for transportation of all

goods bought directly by persons. An additional 36 percent was required indirectly by PCE.

The interdependence of the indus-- tries in the economy can be seen by the fact that even though an industry's production for persons was of one major type, some demand was generated on account of each of the other types of consumer expenditures. For example, the deliveries of the coal mining industry (number 7) to persons fall in the nondurable category and comprised 10 percent of the total output of the coal industry. However, 7 percent of this industry's output was required indirectly by personal expenditures on durables and 20 percent was required indirectly by expenditures on services. Some of the products of the paper industry (number 24) are nondurable expenditures of persons; these direct purchases accounted for 8 percent of the output of the paper industry. However, PCE on durables accounted indirectly for 10 percent of the paper industry's output, and expanditures on services accounted for 14 percent.

Conversion of PCE Data to Input-Output Form

IN order to determine the output required from each industry for a specified level and composition of personal consumption expenditures, it is necessary to prepare the consumption expenditure data in 1958 prices and in the industry classifications of the 1958 input-output table. The information on the industrial composition of PCE appearing in this article provides an important tool for translating expenditure data as they appear in the national accounts into the industry groupings of the input-output table. It should be understood that the industrial composition applicable to the year 1958 may require modification when used to analyze expenditures for other years.

The estimates of PCE to be studied may be developed at various degrees of aggregation, depending on the problem under investigation, the resources available, and so on.

If only the total of PCE is given, the analyst may use table 3, column 1, which shows the industrial composition of total expenditures for personal consumption. Where PCE is given in terms of durables, nondurables and services, the breakdowns shown in columns 2, 3, and 4 of table 3 would be useful.

Table 5.—Personal Consumption Expenditures in Purchasers' Prices, Classified by Industry and by Relative Importance of Each Industry in Each PCE Category, 1958

categories shown in table 1 of this article. These breakdowns could be used with independent estimates of the aggregate value of each of the 12 major categories.*

If PCE is known for each of the 83 categories shown in the annual GNP accounts, the producers' values in table 1 could be used to classify, by industry, the value of each PCE category. This method—the 83-category method—makes use of the finest detail available from published series on PCE. Furthermore, the 83 categories provide substantial flexibility for the analyst since they can be recombined to any level of aggregation. Table 1 is also of use where the problem under analysis concerns only selected categories.

All of these alternatives assume, in varying degrees, stability in the industrial composition of PCE. Detailed as the 83-category method is, its use would not, of course, take account of changes in industrial composition within a PCE category from 1958 to the period under consideration. For example, the 1958 industrial composition of "kitchen and other household appliances" (category V-2), if applied to a year after 1958, would probably underestimate the purchases of air conditioners from industry 52 and overestimate the purchases of other household appliances from industry 54. Under such circumstances, regardless of what level of aggregation of PCE is used, the analyst may find it desirable—depending on the nature of his problem—to make explicit changes in the industrial composition of one or more categories. with appropriate changes in the transportation and trade margins for the category.

Let us assume that the analyst has classified PCE into the 83 categories and now wishes to estimate its industrial composition. The following procedure would be used:

(1) Convert the value for each of the categories to 1958 prices by dividing total expanditures in purchasers' prices by a price index on a 1958 base. Price

Nove.-Detail may not add to total due to rounding.

Source: U.S. Department of Commerce, Office of Business Economics.

^{8.} Table C in the November 1964 orticle used groupings that are being revised slightly. Of the 12 estageries, changes were confined to shifte from colegory VI to category VII.

Table 8 shows the changes that took plane in the Industrial composition of each FOE estagory from 1947 to 1968 in purchasers' prices.

deflators are published in the national accounts for broad groups of PCE. Detailed price indexes are available from basic, sources such as the BLS Consumer Price Index.

- (2) For each consumption category, prepare a percent distribution of producers' values. Such a distribution for each category can be obtained from the first column of table 1 if the first column is extended (as shown in the next 3 columns) to include total transportation margins (industry 65), total trade margins (industry 69), and insurance charges (industry 70).
- (3) Multiply the deflated value of expenditures obtained in step 1 by the percent distribution obtained in step 2.
- (4) For each industry, sum the resulting values.

If more aggregated alternatives are used, step 2 is unnecessary since a complete breakdown of producers' values for all industries (including transportation and trade) is available in table 3 of this article or in table C of the November 1964 article.

Although the problem of industry mix within a PCE category is one which the analyst must be constantly aware of, its importance should not be exaggerated because many categories consist entirely or in large part of a single industry. Of the total value of sales to persons in 1958 (measured in purchasers' prices), 34 percent was classified in PCE categories where a single industry comprised 100 percent of the category; 18 percent was classified in categories where one industry comprised 90 to 99.9 percent of the category, and 33 percent fell in categories where one industry comprised 80 to 89.9 percent of the category. Only 15 percent of the value of industry sales to persons fell in categories where one industry comprised less than 80 percent of the value of the category. The detail for each industry is shown in table 5.

Each entry (in purchasers' prices) within each category in table 1 was allocated to one of the first four columns in table 5, according to the percent of the total value of the category represented by the entry. For example, the first entry for the apparel industry (number 18) in table 1 appears in category II-3a, where it comprises 87 percent of the category. Accordingly,

deflators are published in the national Table 7.—Industrial Composition of Personal Consumption Expenditures in Purchasers' Prices, 1947 and 1953

'The numbering scheme of the personal consumption expanditure categories coveresponds to the table 'Personal Consumption Expanditures, by Type of Product' to be published in a fortherning supplement to the Surviv or Courseof Business. With the exceptions tootboatd, the category numbers also correspond to table 4 in the Trily 1604 Surviv. Expanditure categories VII-6 and XII-3 in the July 1664 table have been omitted because they are no longer included in personal consumption expanditures.

Industry number relates to the numbering scheme used for the 1998 impationity study. For name and Standard industrial Classification (SIC) coverage of each industry, see the table at the end of this article.

The entries for this industry are not exactly comparable. See feetnote 7 and appendix for arnhanation.

for explanation.

1 Change in definition from old category V-8c, Water.

*Change in definition from old category VII-1, Brokerage charges and interest, and investment connection.

*Functual and burial expanses, formerly numbered VI-8.

*Functual and burial expanses, formerly numbered VI-8.

*Imported cars do not appear as a parchase from the import industry (number 80) but are included in the spotor verticles industry (number 80). The import data on antes and parts used for the 1988 input output study did not distinguish between assembled and unassembled cars. The total value of such imports was transferred to industry 59 for distribution.

illustration of the United States by foreigners, formerly numbered XII-4.

Does not correspond to old category XII-4.

Source: U.S. Department of Commerce, Office of Business Becommiss.

this value of \$11.596 million was allocated to column 3 of table 5. The second entry for this industry (\$6,715 million) appears under category II-3b in table 1 and comprises 94 percent of the category; it was, therefore, allocated to column 2 of table 5. The next entry for industry 18 (\$19 million) appears under category II-4 and constitutes 33 percent of the category; therefore, it has been allocated to column 4 of table 5. The last entry (\$19 million) appears under category V-5 and comprises 75 percent of the total, so it too was allocated to column 4 of table 5.

Comparison of approaches

For illustrative purposes, the industrial composition of total personal consumption expenditures in 1964 has been estimated by the four different approaches described above. Each approach involved the use of revised 1964 figures (in 1958 prices) for PCE, at varying levels of aggregation, as follows: first, total PCE; second, durable

goods, nondurable goods and services; third, the 12 major categories of PCE; and finally, the 83 categories of PCE. In each approach, the 1958 industrial composition of the various categories was held constant. Table 6 presents (in percentage terms) these alternative estimates of the industrial composition of 1964 PCE.

It seems reasonable to assume that the 83-category method yields the best approximation to the "correct" industrial composition in 1964, and for this reason, it was used as a standard of comparison. This standard in itself may be subject to some error. For each approach, the percent difference from the 83-category standard was computed, industry by industry. These percent differences without regard to sign were then averaged for all industries, first on an unweighted basis and then on a weighted basis, using the 83-category estimates for the various industries as weights. Summary results are shown in the text table below.

· ·			Perotni	
	Total	PCB	Durobles, non- durables, and services	12 major categories of PCB
Unweighted average !.		11.8	8.4	8.6
Weighted average !		e.s	4.5	4.8

Industries of less than 0.01 percent in column 4 of table 6 were excluded from the averages.

As might have been expected, the use of the 1958 industrial composition of total personal consumption to estimate the 1964 composition yields results inferior to the two less aggregated approaches (the 3-category breakdown and the 12-category breakdown). It is also apparent that, in this particular example, the estimates from the 12-way breakdown are not significantly different from those from the 3-way breakdown.

In comparing the performance of the latter two approaches with each other, it is important to remember that 1958 was a year of mild recession: in constant dollars, expenditures on

durable goods were relatively low and expenditures on nondurables were relatively high, as compared with 1964. Services were about the same proportion of the total in both years. The 12-category breakdown does not isolate the three types of expenditure but combines two or more of them in some categories. The 3-category breakdown is homogeneous in this respect; although it is more highly aggregated than the 12-

category breakdown, it has the advantage of a separation of expenditures into groups with different responses to the business cycle.

It is also evident from this example that the percent differences are largest for the industries of small value in PCE; the unweighted average percent difference is greater than the weighted average in each of the three approaches shown in the text table.

Comparison of 1947 and 1958

IN order to illustrate the extent to which the industrial composition of personal consumption expenditures has changed over time, two tables are presented comparing 1947 and 1958. Such information may provide useful insights in estimating the industrial composition of PCE for years other than 1958. It is important to note that both of the tables are based on nurchasers' prices.

The first, table 7, shows the industrial composition of total PCE in 1947 and 1958, in the prices of their respective years and in 1958 prices. Differences in industry composition in the two years, based on constant dollar data. reflect shifts in the relative importance of the 83 categories of PCE, industry shifts within each of the PCE categories. and estimating errors. The second table, number 8, shows for 1947 and 1958 the industrial composition of each PCE category based on constant (1958) dollars. It therefore isolates the changes in industrial composition within each category of PCE from changes in the relative importance of the various PCE categories in the total. Estimating errors also affect the comparison in table 8.

The 1947 figures in both tables 7 and 8 were based on the 1947 Interindustry Study of the Bureau of Labor Statistics. The adjustments required to make the 1947 data correspond to the concepts of the 1958 flow table are described in the appendix below.

Appendix

UNPUBLISHED data from the 1947 Interindustry Relations Study of the Bureau of Labor Statistics and the official. personal communition expenditure series of the National Locome Division is provided the bases for the 1947 distributions by industry shown in this action. Unlike the 1958 input-output study, the 1957 study had not been integrated with the national income and product acquirits, so that adjustments were necessary to make the 1947 figures conform, as nearly so possible, to the concepts of the national accounts and the 1969 table. A tabulation giving the allocations to the pertonal sector from each industry by PCE category was available as a hyproduct of the 1947 input-output study. Even when all adjustments were made to reorganize the 1947 input-output allocations late the connects of the 1966 table, minor differences remained between the 1947 input-cuput affectations to a given PCB category and the National Income Division's estimate for that measury. These were

(Continued on page #8)

^{10.} To be published in a farthcoming supplement to the Survey.

PCE in the 1958 Input-Output Study

(Continued from page 20)

eliminated by prouting the National Income Division's figures for 1947 for each PCE eategory among the industries contributing to the given PCE category in accordance with the rewrited 1947 input-cuput allocations. In this way, the values for each PCE category and for total personal consumption were made to accord with the official series; however, statistical difficulties in recasting the 1947 data into the 1956 framework may still affect the comparison of 1947 and 1945 industrial composition shown in tables 7 and 6.

A major difference between the two studies was the industry classification scheme. In the 1997 study, the commy was divided into 193 industries, called the Emergency Model (EM) coding scheme. These EM industries were defined in terms of 460 industries for which the basic flows were auslysed, and these in term were defined in terms of the classifications used in the 1947 Comms of Manufactures. Through the use of the cross-classification between the 1947 and 1869 Standard Industrial Classification, it was possible to assign most EM industries to the appropriate 1968 input-output (L-O) industry. In some cases, an EM industry covered two or more L-O industries. The specific products of these EM industry were identified and assigned to the proper L-O industry.

"Competitive Imports" were treated differently in the two studies. In the 1947 study, imports that were similar to domestic products—competitive imports—were transferred to their domestic counterpart industry and were treated as it sold by the domestic industry. In 1968, only competitive imports destined for intermediate consumption were transferred in this way. Imports sold in final merkets in substantially the same form as they were imported were shown as purchased directly knon industry 80 (gross imports). With the detail available from the 1947 analysis, 1947 competitive imports that were of the same type as those directly allocated in 1983 were identified, taken out of their domestic counterport industry, and essigned to 1-0 industry so. This was done separately for each PCE category.

Several food itsent required adjustment for comparability. In the 1947 study, positry and meat stangitured on arms, whether for sele or for home consumption, were allocated directly to the personal sector; in the 1955 study, these items were treated assectatory products of farming and transferred to industry 14 (food and kindred products). For 1947, it was necessary to reallocate such purchases by persons to industry 14. In the 1947 study, milk was treated as an allocation directly from the farm sector to the consumer, with the processing of milk shown as a purchase from retail trade. In the 1968 study, milk processing was an activity of food and kindred products (industry 14). The 1947 purchasers' value of milk was taken out of the form sector and allocated to industry 14 in the PCE estegories that included it.

In the 1947 study, eaking and drinking places were a separate processing sector that purchased food and other goods, puld wages, and seld meets to consumers. In 1938, eating and drinking place setivity was treated as a trade margin. To put the 1947 figures on a basis comparable with the 1958, the 1947 inputs of food to eating and drinking placed ware identified; these were than shown as allocations directly to persons. All other inputs to eating and drinking places were treated as margins; a pro rate share of the margin was aktributed to each food item to entre at purchasers' value of food bought through eating and drinking places.

In the 1947 study, food for hished to government and caramercial employees and olothing issued to the military were included in the purchases of the appropriate purchasing industry or of the government, depending on who did the purchasing. To make these items conform to 1968 concepts, they were included in POE. The imputed food was classified in two ways. The government share was distributed in accordance with Federal Government purchases of food as about in the records of the 1847 study, though this distribution reflects mainly purchases for the military. No attempt was made to adjust for the possibly different distribution of food furnished State employees. The commercial there was broken down by the 1947 distribution of "food for off-premise consumption." For 1947, clothing issued to the military was distributed in accordance with the 1858 hreakdown.

The treatment of scrap, used, and secondisand goods differed in the two studies. In the 1947 study, there were no

test purchases by any final demand sector from the "used-goods" industry; all transactions involving such goods were pretioned to be within the personal sector. Only the margin on each sales was insecured and shown as a purchase by persons from the trade industry. As indicated above (see Footnois 7), the treatment of used goods in the 1958 study was different. This noncomparability, which was of miner statistical importance, was allowed to stand except in the case of used cars. The 1947 figure for used cars was adjusted to conborn to the concept of the 1958 study.

Travel and entertainment expenditures were not divided between business and consumers in the 1947 study. All such purchases were considered to be made by the personal sector. The 1988 study separated the business and consumer shares of travel and entertainment, with PCE reflecting only the personal share of such expenditures. Using detail underlying the 1947 PCE estimates, the 1947 data were adjusted to make the travel and entertainment expenditure data conform to the concepts of the 1958 table.

Nonlife fustrance was conceptually different in the two studies, being measured as gross premiums earned in the 1947 study and as premiums earned less benefits paid in the 1968 study. The 1947 data were adjusted to masform to the 1968

The adjusted 1947 data were converted to 1988 prices in the detail shown in table 8 of this article, that is, for each industry within a PCE exitgory. The defastors used by the Nedonal Income Division were used in this price adjustment, disagregated where necessary in order that the detailed price indexes could be assigned to I-O industry chestifications. Because products of the smaller industries often were not represented in the overall defastor for a PCE category, additional price indexes from the Consumer Price Index and the Wholesale Price Index of the Burean of Labor Statistics were used. Because of the use of these additional agrics, the defasted values for some PCE categories may not agree excelly with the afficial deflated values of the National Income Division.

Developments in the Auto Market

(Continued from page 6)

1963, there have been reductions in output of cars in the lower price lines, those with before-tax prices of \$2,000 or less (with standard equipment) and those in the \$2,000 to \$2,200 range. Production of both price lines combined fell from 28 percent of total auto output in the 1963 model year to 23 percent in 1964 and 20 percent in 1965.

In the first half of 1965, almost three-fourths of the new cars sold had V-8 engines, as compared with about one-half in 1961; 23 percent of new cars sold had factory-installed air-conditioning (8 percent were so equipped in 1961). About 60 percent had power steering (less than 40 percent in 1981), and 80 percent had automatic transmission, a feature that had already become popular by 1961, when 73 percent of new cars were so equipped.

Shifts in the auto market

As can be seen in chart 4, the outstanding change in the auto market in recent years has been the growing proportion of "intermediates" and

"sport-type" compacts at the expense of other compacts and standard-size cars. The market penetration of imports improved slightly in 1965, continuing the fractional gains enjoyed since the recent low in 1962.

Although standard-size cars still account for a major share of the market. they have slipped from 68 percent in the 1960 model year-the year the compacts were introduced-to 53 percent in the model year just ended. Compacts as a group, after rising from 24 percent in 1960 to 34 percent in 1962, fell back to 22 percent in the 1965 model year. This decline might well have been larger had there not been a growing demand for sport-type compacts. These cars, which accounted for 9 percent of the 1965 market as compared with 2 percent in 1961, have sports-car exteriors and bucket seats and are generally available with four-speed transmissions and highperformance engines. Each of the four American auto manufacturers now produces a sports compact, and at least one manufacturer has scheduled the introduction of still another sports compact next apring. In the 1985 model year. one of these cars—the Mustangranked third in sales, coming behind two standard-size cars.

The intermediates—cars that are between compacts and standards in wheel base and overall length—have increased their share of the market from 5 percent in 1962, their first year of production, to 19 percent in 1965. In this period, the number of intermediate brands offered to the public has proliferated, with the introduction of new brands and the lengthening of formerly compact-size models. For the 1966 model year, the Ford Motor Co. has lengthened one of its compacts to intermediate size.

Imported cars accounted for almost 6 percent of the total U.S. car market in 1965. Over two-thirds of total car imports were Volkswagens, which outsold several established domestic makes. All other foreign cars combined now account for a smaller share of the market than they did in 1957, before the 1958-60 boom in imported car sales.
